Problem 3 Function 6: B(x, y) Beta Function Mahavir Patel 40198619

Date: 05/07/2022

1 Algorithm 1 - Tail Recursive Factorial Function

The gamma function is utilised by the beta function to calculate positive integers. The factorial of the number makes it simple to determine the Gamma Value of a positive integer.

$$B(x,y) = \frac{\Gamma x \Gamma y}{\Gamma(x+y)}$$
 where $\Gamma x = (x-1)!$

1.1 Advantages

- The algorithm Gives the accurate answers for the positive integers.
- The execution speed of the tail recursive function compared to recursive function is very fast and memory efficient.
- This algorithm makes it simple to calculate the integer's beta values.

1.2 disadvantages

- Can be used for only Positive numbers.
- Only calculate the Beta Values for the integer
- It does not Consider decimal numbers.

1.3 Why Tail Recursive Function?

If a function concludes by returning the result of the recursive call, it is considered tail-recursive. It is a waste of memory to keep the caller's frame on the stack after the recursive call returns its value because nothing else has to be done. Therefore, the current frame can be used for the call rather than allocating a new one. And for the small value of the integer sometimes recursive factorial faction can cause StackOverFlow error that's why it's better to use the tail recursive function.

1.4 Algorithm

```
Algorithm 1 Calculate Beta Function using factorial
                                                                        \triangleright where x, y \in Z^+
Require: value: x > 0 \& y > 0
Ensure: result = Beta(x, y)
 1: procedure BetaFunction(x, y)
       value1 \leftarrow \text{CalculateGamma}(x)
       value2 \leftarrow CalculateGamma(y)
 3:
 4:
       value3 \leftarrow \text{CalculateGamma}(x+y)
       betaValue \leftarrow \frac{value1*value2}{value3}
 5:
       return betaValue
                                                                ▷ It returns the beta value
 7: end procedure
 8: procedure GAMMAFUNCTION(value)
       value \leftarrow value - 1
10:
       return Factorial(value)
                                                             ▷ It returns the gamma value
11: end procedure
12: procedure FACTORIAL(value)
       return Factorial Tail Recursive (value, 1)
13:
                                                           ▶ It returns the factorial of the
   number
14: end procedure
15: procedure Factorial Tail Recursive (value, n)
       if value = 0 then
                                                         ▶ Return factorial of the number
           return n
17:
       else
18:
           return Factorial Tail Recursive (value - 1, value * n)
19:
                                                                            ▶ tail recursive
    call to function
       end if
20:
21: end procedure
22: result \leftarrow CALCULATEBETA(x, y)
                                                               \triangleright Final result of Beta(x, y)
```

2 Algorithm 2 - Stirling's approximation

The gamma Stirling's approximation, also referred to as Stirling's formula is a mathematical approximation for factorials for decimal values and can be used to construct the beta function for decimal numbers. Since it is a good approximation, it delivers correct results even for small values of n.

$$B(x,y) = \frac{\Gamma x \Gamma y}{\Gamma (x+y)}$$
 where, $\Gamma n = \sqrt{2\pi n} \cdot (\frac{n}{e})^n$

2.1 Advantages

- The algorithm Gives the answers for the positive real numbers.
- Most values that are available can be computed by the algorithm.
- It is possible to apply this approximation approach in place of the integration function to reduce the complexity of the code

2.2 disadvantages

- The algorithm is unable to produce reliable answers.
- Although the complexity is decreased, the earlier algorithm is still substantially more difficult.
- The code cannot be easily debugged.
- The mismatch between the necessary and actual answers is much different for smaller values. However, the difference gets smaller as the size of the numbers grows.

2.3 Why to use Stirling's Approximation?

To calculate the Beta value of the decimal number, it's hard to compute using the gamma integral function. However, Stirlings' approximation can be applied to reduce the complexity. Even for small numbers, this is a good approximation procedure that yields accurate answers. The best outcome is always obtained through approximation. The comparison of Stirling's approximation and the factorial is provided below.

2.4 Algorithm

```
Algorithm 2 Calculate Beta Function using Stirlings's approximation
```

```
\triangleright where x, y \in R^+
Require: value: x > 0 \& y > 0
Ensure: result = Beta(x, y)
 1: procedure CALCULATEBETA(x, y)
        value1 \leftarrow \text{CALCULATEGAMMA}(x)
        value2 \leftarrow \text{CalculateGamma}(y)
 3:
        value3 \leftarrow \text{CalculateGamma}(x+y)
 4:
        beta \leftarrow \frac{value1*value2}{2}
 5:
        return beta
                                                                       ▶ It returns the beta value
 6:
 7: end procedure
 8: procedure CalculateGamma(value)
        firstPart \leftarrow 2 \cdot \pi \cdot value
 9:
        secondPart \leftarrow (\frac{value}{e})
10:
        gamma \leftarrow \text{CalculatePower}(firstPart, \frac{1}{2})\text{CalculatePower}(secondPart, value)
11:
        return qamma
                                                                    ▶ It returns the gamma value
12:
13: end procedure
14: procedure CalculatePower(value1,value2)
        power \leftarrow math.power(value1, value2)
16:
        return power
                                                               ▶ It returns the base to the power
17: end procedure
18: procedure CalculateLog(value)
        answer \leftarrow 0
19:
        base \leftarrow \frac{value-1}{value+1}
20:
        for i \leftarrow 1,125 do
21:
            exponent \leftarrow 2 * i - 1
22:
            answer \leftarrow answer + \frac{1}{exponent} * \text{CALCULATEPOWER}(base, exponent)
23:
        end for
24:
                                                                   ▷ It returns the value of Log n
        return \ 2 * answer
25:
26: end procedure
27: result \leftarrow CALCULATEBETA(x, y)
                                                                       \triangleright Final result of Beta(x, y)
```

```
Algorithm 3 Calculate the power(x,y)
Require: value: x \& y
                                                                                 \triangleright where x, y \in R
Ensure: result = Power(x, y)
 1: procedure CALCULATEPOWER(base,exponent)
        Convert the exponent into String
 2:
        exponentArray \leftarrow Split \ the \ exponent \ into \ integer \ and \ fractional \ part
 3:
        if exponetArray[1] > 0 then
 4:
            return CalculateFractionPower(base,exponent)
 5:
 6:
        end if
 7:
        if exponent < 0 then
            base \leftarrow \frac{1}{base}
 8:
            exponent \leftarrow (-1) \cdot exponent
 9:
        end if
10:
        if exponent \leftarrow 0 then
11:
            return 1
12:
        end if
13:
14:
        if exponent\%2 \leftarrow 0 then
15:
            base \leftarrow base * base
            exponent \leftarrow \frac{exponent}{2}
16:
            return CALCULATEPOWER(base,exponent)
17:
        else
18:
            exponent \leftarrow \frac{exponent-1}{2}
19:
            return base * CALCULATEPOWER(base * base, exponent)
20:
21:
        end if
22: end procedure
23: procedure CalculateFractionPower(base,exponent)
        answer \leftarrow 0
24:
        logvalue \leftarrow 0
25:
        if exponet \leftarrow 0 then
26:
27:
            return 1
        end if
28:
        if base < 0 then
29:
            logvalue \leftarrow CALCULATELOG(base * (-1))
30:
31:
        else
32:
            logvalue \leftarrow CALCULATELOG(base)
        end if
33:
34:
        if exponent \leftarrow 0 \land exponent > 0 then
            return answer
35:
        end if
36:
        for i \leftarrow 0, 125 do
37:
            numerator \leftarrow CALCULATEPOWER(exponent * logvalue, i)
38:
            denominator \leftarrow Factorial(i)
39:
            answer \leftarrow answer + \frac{numerator}{denominator}
40:
        end for
41:
        if base < 0 \land exponent\%2 \neq 0 then
42:
            return answer * (-1)
43:
        else
44:
                                                 5
45:
            return answer
46:
        end if
47: end procedure
```
